

ABSTRACT OF THE DISCLOSURE

Images recorded on a film can be easily classified and selected for being recorded in a recording medium M. A scanner reads the images from a developed negative film and obtains
5 image data sets. The image data sets are stored in an image storage server. When a user inputs an instruction to display the image data sets from a terminal, an image organizing server classifies the image data sets and carries out selection therefrom. A result thereof is displayed on the terminal.
10 After the result is corrected if necessary, a media drive records the image data sets that have been classified and selected in the recording medium in response to a recording instruction input from the user.
